

# Wallabot Documentation

**Wallabot** is an AI-powered C2C second-hand marketplace built with a FastAPI microservices backend, a Vue 3 frontend, and an LLM-driven agentic subsystem for intelligent product classification and price recommendations.

# Project Overview

## What is Wallabot?

Wallabot is a full-stack **C2C (consumer-to-consumer) second-hand marketplace** inspired by Wallapop. It allows registered users to list products, browse the catalogue, reserve items, and complete peer-to-peer purchases through an integrated digital wallet. The platform is augmented by an AI subsystem — the *Wallabot Agentic Service* — which provides intelligent product category suggestion and live market-based price estimation powered by LangChain LCEL, OpenAI GPT-4o-mini, and Tavily web search.

The project was developed across three sprints by team **BSPQ26-E9** as part of the Software Engineering course at the University of Deusto.

---

## Sprint Deliverables

| Sprint   | Main deliverables                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Sprint 1 | User registration & login, product CRUD, basic catalogue browsing                                                                                                      |
| Sprint 2 | Digital wallet, product reservation with configurable timeout, atomic purchase flow, transaction history                                                               |
| Sprint 3 | AI category suggestion agent, AI price recommendation agent, LangSmith observability tracing, user ratings system, public user profiles, full-text search on catalogue |

---

## Key Features

### User Management & Authentication

- Email and password registration with **bcrypt** password hashing
- JWT-based stateless authentication (HS256) shared across all microservices via a single `SECRET_KEY` environment variable — no inter-service token validation call per request
- Social login via **Google OAuth 2.0** and **Facebook OAuth** using the `authlib` library
- Account linking: a social account is bound to one provider and rejects conflicting link attempts (you cannot link the same email to two different providers)
- Token payload: `{"sub": "<user_email>", "exp": <unix_timestamp>}`

# System Architecture

## Design Philosophy

Wallabot follows a **microservices architecture** where each business domain is encapsulated in an independently deployable FastAPI service. Services share no databases and communicate only via HTTP REST. The Vue 3 frontend is the sole public entry point and routes every API call through a Vite proxy in development (or Nginx in production) to the appropriate service.

Key design decisions:

- **No shared database** — each service owns its schema; cross-service data access goes over HTTP with service-scoped JWTs
- **Stateless JWT validation** — every service validates tokens locally, eliminating a central auth round-trip per request
- **Append-only ledger** — wallet balance and product state history are immutable, audit-safe records
- **Graceful AI degradation** — agents always return a usable response even when the LLM provider is unreachable

## High-Level Diagram

The Agentic Service has **no database** — every request is stateless and fully self-contained.

# REST API Reference

Wallabot exposes its functionality through four independent HTTP REST services. This section documents every public endpoint, request/response schema, and error contract — the equivalent of an RMI interface specification.

All services accept and return **JSON** ( `Content-Type: application/json` ). Endpoints that require authentication expect a `Bearer` token in the `Authorization` header issued by the Auth Service.

# Auth Service API

Base URL (local): `http://localhost:8001` Base URL (production): configured via `AUTH_SERVICE_URL` environment variable

The Auth Service owns user identity: registration, login, social OAuth, JWT issuance, public user profiles, and the ratings system.

---

## Authentication

Most endpoints in other services require a JWT access token issued by this service. Pass it as a Bearer token in every request:

```
Authorization: Bearer <access_token>
```

Tokens are signed with `HS256` using the shared `SECRET_KEY` environment variable and contain `{"sub": "<user_email>"}` as the payload subject.

---

## Health Check

**GET /health**

Returns the service liveness status. Used by Docker healthcheck probes.

Response 200

```
{ "status": "ok" }
```

---

# Inventory Service API

Base URL (local): `http://localhost:8002`

The Inventory Service owns the product catalogue: creating, reading, updating, and deleting listings, plus image uploads. Products stored here represent the *listing* view; the Transaction Service maintains a separate copy for commerce state.

## Health Check

**GET** `/health`

```
{ "status": "ok" }
```

## Products

**GET** `/api/v1/products`

Returns a list of all products, optionally filtered. No authentication required.

### Query parameters

| Parameter              | Type                                                                                                 | Description                                           |
|------------------------|------------------------------------------------------------------------------------------------------|-------------------------------------------------------|
| <code>state</code>     | <code>Available</code>   <code>Reserved</code>   <code>Sold</code>                                   | Filter by availability state                          |
| <code>category</code>  | string (min 1 char)                                                                                  | Filter by category name (case-insensitive)            |
| <code>min_price</code> | float ( $\geq 0$ )                                                                                   | Minimum product price in EUR                          |
| <code>max_price</code> | float ( $\geq 0$ )                                                                                   | Maximum product price in EUR                          |
| <code>condition</code> | <code>New</code>   <code>Like New</code>   <code>Good</code>   <code>Fair</code>   <code>Poor</code> | Filter by item condition                              |
| <code>q</code>         | string (min 1 char)                                                                                  | Full-text keyword search across title and description |

Response 200 — array of `ProductOut`

# Transaction Service API

Base URL (local): `http://localhost:8003`

The Transaction Service owns the commerce domain. It manages a digital wallet per user, coordinates product reservations (with automatic timeout expiry), and processes purchases via atomic wallet debit operations. It also exposes transaction history.

All endpoints require authentication ( `Authorization: Bearer <token>` ).

---

## Health Check

**GET** `/health`

```
{ "status": "ok", "service": "transaction-service" }
```

## Wallet

**GET** `/wallet/balance`

Returns the authenticated user's current wallet balance in EUR.

Response 200

```
{ "balance": 250.00 }
```

**POST** `/wallet/deposit`

Adds funds to the authenticated user's wallet.

Request body

# Agentic Service API (Wallabot)

Base URL (local): `http://localhost:8004`

The Agentic Service is the AI subsystem of Wallabot. It provides two intelligent endpoints that assist sellers when creating a product listing: automatic category classification and market-based price estimation.

All endpoints are **stateless** — each request is self-contained with no memory of prior calls. Authentication is **not required** to call these endpoints.

---

## Health Check

**GET** `/health`

```
{ "status": "ok" }
```

## Category Suggestion

**POST** `/wallabot/category`

Classifies a product into one of the caller-provided categories using a LangChain LCEL chain backed by **GPT-4o-mini**.

The agent selects the most appropriate existing category. It only proposes a new category name (setting `is_new_category: true`) when none of the provided options is a good fit.

On output validation failure the agent retries up to **3 times** with progressively detailed correction feedback. On LLM provider failure it returns the closest available category with `confidence: 0.0` rather than raising a 5xx error.

# Wallabot AI Agent

The Wallabot Agentic Service ( `backend/agent-service/` ) is the AI subsystem of the marketplace. It is an independent FastAPI microservice that exposes two intelligent endpoints to assist sellers when creating a product listing:

- `POST /wallabot/category` — automatic product category classification
- `POST /wallabot/price` — market-based price estimation in EUR

Both are powered by [LangChain LCEL](#), OpenAI **GPT-4o-mini**, and the **Tavily** web search API. Every call is stateless — no session or memory is kept between requests.

## Architecture Overview

# Testing & Quality

## Overview

Wallabot enforces a **50% minimum code coverage** threshold across all backend services. The CI pipeline fails if any service falls below this threshold. All four services exceed this threshold significantly — the current measured coverage, obtained by running the full test suite locally, is summarised below.

## Coverage Summary

| Service             | Tests | Lines covered | Coverage |
|---------------------|-------|---------------|----------|
| auth-service        | 34    | 331 / 415     | 80%      |
| inventory-service   | 44    | 267 / 301     | 89%      |
| transaction-service | 57    | 511 / 619     | 83%      |
| agentic-service     | 75    | 277 / 318     | 87%      |
| Total               | 210   | 1 386 / 1 653 | 84%      |

Coverage is measured with `pytest-cov` against each service's `app/` package. The 50% minimum threshold is enforced by `--cov-fail-under=50` in every test run.

## Per-Service Breakdown

### Auth Service — 80%

Run:

```
cd backend/auth-service
pytest --cov=app --cov-report=term-missing -q
```

| Module                   | Stmts | Miss | Cover |
|--------------------------|-------|------|-------|
| <code>api/deps.py</code> | 10    | 0    | 100%  |

# DevOps & CI/CD

## Docker Compose (Local Development)

The `docker-compose.yml` at the project root starts the full stack locally.

```
cp .env.example .env # fill in secrets
docker compose up --build
```

Services and ports:

| Service             | Internal port | Exposed port |
|---------------------|---------------|--------------|
| auth-service        | 8000          | 8001         |
| inventory-service   | 8000          | 8002         |
| transaction-service | 8000          | 8003         |
| agentic-service     | 8000          | 8004         |
| frontend            | 5173          | 5173         |

All backend containers share the `wallabot-net` Docker network and the `wallabot-data` named volume that persists SQLite database files.

## Environment Variables

Copy `.env.example` to `.env` and fill in:

| Variable                                                          | Description                                              |
|-------------------------------------------------------------------|----------------------------------------------------------|
| <code>SECRET_KEY</code>                                           | JWT signing key (shared by all services)                 |
| <code>OPENAI_API_KEY</code>                                       | Required by agentic-service for GPT-4o-mini              |
| <code>TAVILY_API_KEY</code>                                       | Required by agentic-service for web search               |
| <code>SUPABASE_URL</code>                                         | (Optional) Supabase project URL for PostgreSQL + Storage |
| <code>SUPABASE_SERVICE_ROLE_KEY</code>                            | (Optional) Supabase service-role key                     |
| <code>GOOGLE_CLIENT_ID</code> / <code>GOOGLE_CLIENT_SECRET</code> | (Optional) Google OAuth                                  |
